

Case Study: Creating a String Class

Earlier in this book, you were introduced to the C++ standard library string class. The string class automatically handles many of the tedious tasks involved in using strings, such as dynamic memory allocation and bounds checking. It also overloads operators, such as + and =, and offers many member functions that ease the job of working with strings. In this section, however, you will learn to write your own string handling class. In the process, you will see examples of the copy constructor and overloaded operators in full action.

The MyString Class

The MyString class defined in this section is an abstract data type for handling strings. It offers several advantages over standard C++ character array manipulation:

- Memory is dynamically allocated for any string stored in a MyString object. The programmer using this class doesn't need to be concerned with how large to make an array.
- Strings may be assigned to a MyString object with the = operator. The programmer using this class does not have to call the strcpy function.
- One string may be concatenated to another with the += operator. This eliminates the need for the strcat function.
- Strings may be tested with the relational operators. The programmer using this class doesn't have to call the strcmp function.

The following program listings show the class implementation:

Contents of MyString.h

```

296     return strm;
297 }

```

The Copy and Move Constructors

Because the `MyString` class has a pointer as a member and dynamically allocates memory to store its string value, a copy constructor and a move constructor are provided. These constructors will cause the object to properly set up its data when initialized with another `MyString` object.

The Overloaded = Operators

The `MyString` class has three overloaded `=` operators. The first is a copy assignment operator, for assigning one `MyString` object to another. This operator function is called when the operator and on the right of the `=` sign is a `MyString` object, as shown in the following code segment:

```

MyString first("Hello"), second;
second = first;

```

The second version of `MyString`'s `=` operator is a move assignment operator. It is called when the operand on the right side of the `=` operator is an rvalue `MyString` object. For example, an object that is returned from a function.

The third version of `MyString`'s `=` operator is for assigning a traditional C-string to a `MyString` object. This operator function is called when the operand on the right of the `=` sign is a string literal or any pointer to a C-string (such as the name of a char array). This is shown in the following program segment:

```
MyString name;
char who[] = "Jimmy";
name = who;
```

The Overloaded += Operators

The `+=` operator is designed to concatenate the string on its right to the `MyString` object on its left. Like the `=` operators, `MyString` has two versions of `+=`. The first version is designed to work when the right operand is another `MyString` object, as shown in the following program segment:

```
MyString first("Hello "), second("world");
first += second;
```

The second version of the `+=` operator will be called when the right operand is a literal string or any pointer to a character. It is shown here:

```
MyString first("Hello ");
first += "World";
```

The Overloaded == Operators

The `MyString` object has overloaded versions of the `==` operator for performing equality tests. Like the other operators, the first version is designed to work with another `MyString` object, and the second is designed to work with a traditional C-string.

The `==` operator functions return an integer that can be treated as a Boolean value. Both functions use `strcmp` to compare the operands, then returns the negative of `strcmp`'s return value. (Recall that `strcmp` uses inverted logic: It returns 0 when its arguments are equal, and returns a nonzero value when they are not equal.) So, these operator functions return true if the string contained in the right operand matches the `str` member of the calling object. If the strings of the two operands do not match, the functions return false. These operator functions allow the programmer using this class to construct relational expressions, such as those shown in the following program segments:

```
MyString name1("John"), name2("John");
if (name1 == name2)
    cout << "The names are the same.\n";
else
    cout << "The names are different.\n";

MyString name1("John");
if (name1 == "Jon")
    cout << "The names are the same.\n";
```

```
else
    cout << "The names are different.\n";
```

The Overloaded > and < Operators

The `MyString` object has two overloaded versions of the `>` operator for performing greater-than tests, and the `<` operator for performing less-than tests. The first version of each is designed to work with another `MyString` object, and the second is designed to work with a traditional C-string. (The functions use the library function `strcmp` to determine if a greater-than or less-than relationship exists.)

The `>` functions return a `true` if the `str` member of the calling object is greater than the string contained in the right operand. Otherwise, the functions return `false`. The `<` functions return a `true` if the `str` member of the calling object is less than the string contained in the right operand. Otherwise, they return `false`.

These operator functions allow the programmer using this class to construct relational expressions such as those shown in the following program segments:

```
MyString name1("John"), name2("Jon");
if (name1 > name2)
    cout << "John is greater than Jon.\n";
else
    cout << "John is not greater than Jon.\n";
MyString name1("John");
if (name1 < "Jon")
    cout << "John is less than Jon.\n";
else
    cout << "John is not greater than Jon.\n";
```

The Overloaded >= and <= Operators

The `MyString` object has two overloaded versions of the `>=` operator for performing greater-than or equal-to tests, and the `<=` operator for performing less-than or equal-to tests. The first version of each is designed to work with another `MyString` object and the second is designed to work with a traditional C-string. (The functions use the library function `strcmp` to determine if a greater-than or less-than relationship exists.)

The `>=` functions return a `true` if the `str` member of the calling object is greater than or equal to the string contained in the right operand. Otherwise, the functions return `false`. The `<=` functions return `true` if the `str` member of the calling object is less than or equal to the string contained in the right operand. Otherwise, they return `false`.

These operator functions allow the programmer using this class to construct relational expressions, such as those shown in the following program segments:

```
MyString name1("John"), name2("Jon");
if (name1 >= name2)
    cout << "John is greater than or equal to Jon.\n";
else
    cout << "John is not greater than or equal to Jon.\n";
```

```

MyString name1("John");
if (name1 <= "Jon")
    cout << "John is less than or equal to Jon.\n";
else
    cout << "John is not less than or equal to Jon.\n";

```

Program CS4-1 shows how MyString's += operator performs string concatenation. Additionally, the program's source code demonstrates how MyString allows the programmer to treat strings much like any other built-in data type.

Program CS4-1

```

1  // This program demonstrates the MyString class.
2  #include <iostream>
3  #include "MyString.h"
4
5  int main()
6  {
7      // Define and initialize several MyString objects.
8      MyString object1("This"), object2("is");
9      MyString object3("a test.");
10     MyString object4 = object1;
11     MyString object5("is only a test.");
12     // Define a C-string.
13     char string1[] = "a test.";
14
15     // Display the MyString objects.
16     cout << "object1: " << object1 << endl;
17     cout << "object2: " << object2 << endl;
18     cout << "object3: " << object3 << endl;
19     cout << "object4: " << object4 << endl;
20     cout << "object5: " << object5 << endl;
21
22     // Display the C-string.
23     cout << "string1: " << string1 << endl;
24
25     // Test the overloaded += operator.
26     object1 += " ";
27     object1 += object2;
28     object1 += " ";
29     object1 += object3;
30     object1 += " ";
31     object1 += object4;
32     object1 += " ";
33     object1 += object5;
34     cout << "object1: " << object1 << endl;
35
36     return 0;
37 }

```

Program Output

```

object1: This
object2: is
object3: a test.
object4: This
object5: is only a test.
string1: a test.
object1: This is a test. This is only a test.

```

Program CS4-2 shows how MyString's relational operators can be used to compare strings with the same ease that numeric data types are compared.

Program CS4-2

```

1 // This program demonstrates the MyString class.
2 #include <iostream>
3 #include "MyString.h"
4 using namespace std;
5
6 int main()
7 {
